

- 1) `var` → old way of declaring variables. It is function-scoped and can be redeclared.
`let` → block-scoped and value can be changed.
`const` → block-scoped and value cannot be reassigned.

In my project

- I used `const` for API URLs and fixed values
- I used `let` for changing form data and counters.
- I avoided using `var` because `let` and `const` are safer.

- 2) An event is an action performed by the user such as:

- * button click
- * form submit
- * typing in input
- * mouse hover

- 3) `LocalStorage` is used to store data in the browser permanently until it is manually cleared.
Example:

```
localStorage.setItem('user', JSON.stringify(
    userData));
```

```
const data = JSON.parse(localStorage.getItem('user'));
```

In my project:

- * I stored registered user details in localStorage.
- * During login, I checked entered data with stored data.
- * It helped keep user data even after page refresh.

4) Synchronous: Code runs line by line
Asynchronous: Code does not wait for long operations like API calls

5) `map()`
Returns a new array.
Mostly used in React UI rendering

for each `li`:

Only loops through array.

Does not return a new array

React - Project

1) React is a JavaScript library used to build user interfaces

Why I used React:

- * Reusable components
- * Faster UI updates
- * Single Page Application support

- 2) `useState` is a React Hook used to store and update data inside a component.

In my project:

I used `useState` for:

- * Form Input values
- * Login State
- * API data Storage

- 3) A controlled component means form inputs are controlled using React State.

In my project:

I handled all form fields using `useState`.

OnChange updated the state whenever the user typed.

- 4) Props are used to pass data from parent component to child component.

In my project:

* I passed user data from parent to child components.

* I used props for table data, form values, and reusable cards.
